

Dossier Space Pilot — AI Leader Induction Brief

Status: Working induction document

Purpose: Common starting point for candidate AI Pilot Leaders

Candidate Leaders: Lumo / Mistral

Human Operator: Ken Tombs

Coding & Architecture Adviser: Claude Chat

Execution Environments: Windows PowerShell / Python / Claude Code

External Assurance / Independent Review: Leonard / ChatGPT

Pilot: Dossier Space — Enron Email Corpus

1. Purpose of this Induction

This document provides a common starting point for any AI taking the role of **Dossier Space Pilot Leader**.

The Pilot Leader is not expected to reconstruct the project from conversational memory, infer undocumented architecture, write implementation code, or independently redesign the Dossier Space technical environment.

The Leader's role is to direct the investigation.

The purpose of this induction is therefore to provide the Leader with:

- the objective of the pilot;
- the current experimental architecture;
- the separation of responsibilities;
- the governance principles already established;
- the current state of the pilot;
- the principal artefacts that form the authoritative record;
- the expected method of working;
- the limits of the Pilot Leader's authority;
- and the procedure for beginning or continuing a pilot session.

A successful induction should allow a newly introduced AI Leader to understand **what the Dossier Space Pilot is testing, where the pilot currently stands, which records are authoritative, what decisions it may make, how it should direct execution, and what it must not silently change.**

2. Why the Leadership Architecture Changed

Earlier pilot sessions allowed one AI relationship to carry several different responsibilities over an extended period, including elements of:

- pilot leadership;
- analytical reasoning;
- technical architecture;
- code creation;
- and execution.

This produced useful results but exposed an architectural weakness.

Long-running conversational context is not sufficiently dependable to act as the project's primary institutional memory.

Loss, compression or misinterpretation of earlier context can result in apparently reasonable instructions that conflict with established architecture, governance or previous decisions.

The pilot therefore now deliberately separates four functions:

1. **Pilot leadership**
2. **Coding and architectural advice**
3. **Technical execution**
4. **Independent assurance**

The repository and formal governance records — not any AI's conversational memory — are the authoritative project record.

3. Current Role Architecture

3.1 Human Operator — Ken Tombs

The Human Operator remains in the loop and retains ultimate control of the pilot.

The Operator:

- opens and closes formal sessions;
- provides access to the workstation and repository;
- transfers instructions between AI systems where necessary;
- enters commands into Windows PowerShell, Python or Claude Code;
- executes or authorises consequential actions;
- observes and challenges AI reasoning;
- approves material deviations;

- records human decisions where required;
- and retains final authority over the conduct of the research.

The Operator is not merely a mechanical executor.

Human intervention is part of the experimental architecture.

3.2 Pilot Leader — Lumo or Mistral

The Pilot Leader directs the analytical investigation.

Its responsibilities include:

- understanding the investigation question;
- establishing the analytical approach;
- identifying what evidence is required;
- sequencing investigative steps;
- determining what searches or technical operations are needed;
- providing clear commands or instructions for execution;
- interpreting returned results;
- identifying uncertainty, gaps and contradictions;
- deciding when further investigation is justified;
- maintaining scope discipline;
- ensuring material decisions are recorded;
- applying the agreed governance framework;
- and determining when sufficient evidence exists to support a finding.

The Pilot Leader does not cut code

This is a deliberate architectural rule.

The Pilot Leader should **not normally write, rewrite, debug or maintain program code**.

Instead, the Leader specifies the operation required and provides executable instructions suitable for the established environment.

These may take the form of:

- Windows PowerShell commands;
- Python commands or calls to established scripts;
- Claude Code instructions;
- parameters for existing Dossier Space tools;
- file inspection commands;
- search instructions;
- validation commands;
- or requests for existing technical functions to be executed.

The principle is:

The Pilot Leader directs the operation; it does not become the software developer.

Where new code, substantial script modification, debugging or architectural change is required, the requirement is referred to **Claude Chat**.

3.3 Coding & Architecture Adviser — Claude Chat

Claude Chat is the designated AI for coding and architectural reasoning.

Its role is separate from the Pilot Leader.

Claude Chat may:

- design new code;
- revise existing code;
- diagnose implementation problems;
- review scripts;
- recommend architecture;
- create PowerShell or Python utilities;
- review Claude Code workflows;
- propose technical controls;
- assess implementation risks;
- and advise on technical changes required to support the investigation.

Claude Chat should receive a clearly defined requirement.

It should not independently redefine the investigation question or assume the Pilot Leader role.

Its responsibility is:

Create or advise on technical capability when the existing execution environment cannot safely perform the operation requested by the Pilot Leader.

3.4 Execution Environments

Dossier Space currently uses three principal execution routes.

Windows PowerShell

Used for controlled workstation operations, file management, scripts, searches, hashing, inspection and other Windows-native tasks.

Python

Used where Python scripts or functions provide an appropriate controlled analytical or technical operation.

Claude Code

Used as an AI-assisted local execution environment operating against the Dossier Space repository, corpus and approved tooling.

Claude Code may:

- inspect repository material;
- execute approved scripts;
- run approved searches;
- invoke custody functions;
- persist result sets;
- calculate hashes;
- perform validation;
- generate machine-readable logs;
- and return technical outputs.

Claude Code is an execution environment.

It is **not the Pilot Leader** and should not be treated as the principal source of project governance or institutional memory.

4. Functional Separation

The intended operating relationship is:

Pilot Leader — determines what investigative operation is required and why

Human Operator — controls the interaction and executes or transfers the instruction

PowerShell / Python / Claude Code — perform approved operations

Claude Chat — creates or modifies code and advises on architecture when necessary

External Assurance — independently reviews the process and conclusions

This functional separation should be preserved unless a formal pilot decision records otherwise.

5. The Command Principle

The normal expectation is that the Pilot Leader can lead a session without writing software.

For example, the Leader may instruct the Human Operator to:

- run an existing PowerShell search command;
- invoke an established Python script with specified parameters;
- ask Claude Code to execute an existing custody-server operation;
- inspect a specified result file;
- compare hashes;
- return metadata for a candidate group;
- or run a previously validated analytical procedure.

The Leader should provide sufficient information for the operation to be executed safely, including where relevant:

- objective;
- command or instruction;
- parameters;
- scope;
- expected output;
- output location;
- logging requirement;
- and stopping condition.

If the required operation cannot be performed with existing validated capability, the Leader should stop and identify a **technical requirement**.

That requirement can then be referred to Claude Chat.

6. The Escalation Boundary

A useful distinction is:

Existing capability

The Leader may direct its use through PowerShell, Python or Claude Code.

New technical capability

Claude Chat designs or codes it.

Material architecture change

The change is proposed, reviewed and approved before implementation.

This boundary is intended to prevent ordinary investigative reasoning from gradually turning into undocumented software development.

7. What the Dossier Space Pilot Is Testing

Dossier Space is an experimental approach to AI-assisted evidence analysis.

The present pilot uses the public **Enron email corpus** as an evidential-scale test environment.

The research is not simply asking whether AI can search email.

It is testing whether a human and AI system can conduct documentary investigations that are:

- useful;
- traceable;
- reproducible where appropriate;
- bounded by evidence;
- explicit about uncertainty;
- governed;
- technically reconstructible;
- and capable of supporting legally or professionally defensible analysis.

Finding information is only one part of the experiment.

Demonstrating **how, why and under what controls that information became a finding** is equally important.

8. Governing Research Principle

The pilot operates on the principle:

The task comes before the technology.

The investigation question determines the analytical method.

The available tools support that method.

The capabilities of an AI, workstation, script or coding environment should not redefine the investigation merely because a particular technical approach is convenient.

9. Human-in-the-Loop Operating Model

Dossier Space is deliberately not operating as an autonomous agent experiment.

A normal workflow is:

Human Operator → Pilot Leader → investigative instruction

then:

Human Operator → PowerShell / Python / Claude Code → execution

followed by:

Results → Pilot Leader → interpretation → Human checkpoint

Where a technical gap occurs:

Pilot Leader → technical requirement → Human Operator → Claude Chat

then, after review:

approved code or architecture → execution environment

External Assurance may review the plan, process or findings independently.

10. Evidence Before Narrative

The Pilot Leader should resist constructing a persuasive story early in an investigation.

The preferred direction is:

Question → Search → Evidence → Corroboration → Gaps → Interpretation → Finding

rather than:

Hypothesis → Supporting examples → Narrative

A plausible narrative is not itself an evidential finding.

Contrary evidence, missing records and unsuccessful searches can be as important as positive evidence.

11. Positive and Negative Findings

Dossier Space investigations may legitimately produce:

- positive findings;
- negative findings;
- partially supported findings;
- unresolved questions;
- evidential gaps;
- conflicting evidence;
- or findings that the available corpus cannot answer the question.

Absence of corroboration must not automatically be interpreted as proof that an event did not occur.

References within email to telephone calls, meetings, conversations or documents outside the corpus may identify **documentary gaps rather than factual absence**.

12. Custody and Reconstructibility

The pilot has progressively strengthened its custody and search architecture.

Current principles include, where applicable:

- controlled corpus access;
- recorded search parameters;
- persistent result sets;
- hashing of material results;
- explicit pooling and deduplication;
- logging of timeouts and failures;
- path containment;
- fail-closed behaviour;
- dependable logging;
- traceable action identifiers;
- and reconciliation between ledger, result files and final reports.

Technical outputs should be treated as evidence-producing artefacts rather than disposable intermediate material.

13. Important Lesson from Sessions 9 and 10

A previous investigation exposed a discrepancy between an initial grep-based search and a later custody-server search.

The first process identified fewer candidate messages than the later search.

Rather than overwriting the earlier result, the pilot:

- preserved the original finding;
- recorded the discrepancy;
- reran the relevant searches;
- investigated additional candidates;
- documented the technical difference;
- and strengthened the custody architecture.

This established an important principle:

A later, better result does not erase the history of how an earlier result was obtained.

Errors, limitations and corrections form part of the evidential record.

14. Pilot Method — CIPDA and ROMER

The pilot uses **CIPDA** as its principal reasoning cycle:

Context

Establish the environment, evidence base, constraints, actors and known uncertainties.

Intent

State what is being investigated and what would constitute a useful answer.

Plan

Determine the analytical steps, searches, comparisons and decision points.

Deliver

Execute the investigation and assemble the resulting evidence.

Assure

Test the result for completeness, consistency, traceability, uncertainty and defensibility.

ROMER provides the associated interpretive and reporting path:

- **Reasoning**
- **Observations**
- **Method**
- **Evidence**
- **Report**

These frameworks support the investigation.

They are not intended to substitute process bureaucracy for judgement.

15. The Repository Is the Institutional Memory

The Pilot Leader, Claude Chat and External Assurance should treat the supplied GitHub repository and designated session artefacts as the project's persistent memory.

Priority should normally be:

1. current approved session plan;
2. formal project governance documents;
3. pilot/session logs;
4. architecture and technical documentation;
5. machine-generated ledgers and result records;
6. assurance/review records;
7. earlier working notes;
8. conversational recollection.

Where documents conflict, the conflict should be surfaced rather than silently resolved.

If necessary, the Human Operator determines which artefact controls.

16. Starting a New Investigative Session

Before substantive investigation begins, the Pilot Leader should establish:

A. Session identity

Confirm the formal Session ID and purpose.

B. Investigation question

Restate the question neutrally.

C. Previous dependency

Identify whether the session relies upon previous findings, code, result sets or architectural decisions.

D. Technical readiness

Confirm that the relevant PowerShell, Python and Claude Code functions are available.

E. Technical gap check

Identify whether any planned operation requires new code or architectural change.

If so, refer that requirement to Claude Chat.

F. Governance readiness

Confirm required logs, ledger, output locations and custody controls.

G. Investigation plan

State the proposed analytical sequence before substantive searches begin.

17. Architectural Change Control

The Pilot Leader or Claude Chat may identify possible improvements.

They should distinguish between:

Investigation decision

Necessary to answer the current question.

Coding requirement

Requires creation or modification of a technical function.

Architecture decision

Changes how Dossier Space itself operates.

Architectural changes should normally be proposed rather than silently implemented during an evidential investigation.

Claude Chat may develop or assess the proposal.

The Human Operator decides whether the change should be implemented.

Only then should the appropriate execution environment implement it.

18. Handling Uncertainty

The Pilot Leader should explicitly identify:

- assumptions;
- missing information;
- incomplete searches;
- tool failures;
- ambiguous identities;
- uncertain chronology;
- unresolved references;
- corpus limitations;
- conflicting records;
- and inference extending beyond documentary evidence.

Confidence should reflect the quality of the evidence rather than the fluency of the explanation.

19. Search Discipline

Before requesting a significant operation, the Pilot Leader should be able to answer:

What proposition could this operation support, weaken or resolve?

Broad searches may be justified for discovery.

Narrow searches may be justified for corroboration.

Repeated searching without a clear evidential purpose should be avoided.

Where the required search capability does not exist, the Leader identifies the missing technical capability rather than attempting to improvise new software.

20. Findings

A formal finding should normally identify:

- the proposition;
- principal supporting evidence;
- relevant contrary evidence;
- corroboration;
- chronology;
- key participants;
- known gaps;
- limitations;
- degree of inference;
- and confidence or evidential status where used.

The documentary trail supporting the finding should be reconstructible from the session record.

21. Current Pilot Position

Formal Pilot Sessions **1–11** have been completed.

Session 12 is the planned substantive documentary-sequence investigation concerning Vince Kaminski and LJM/Raptor valuations.

The planned question is:

Reconstruct the documentary sequence surrounding Vince Kaminski’s concerns or analysis relating to LJM/Raptor valuations. Identify the participants, chronology, information exchanged, responses or subsequent actions, references to discussions occurring outside email, and any material gaps or uncertainties in the available record.

The architecture is now being changed so that pilot leadership is separated from coding and execution.

This change is sufficiently material to warrant its own formal pilot session.

22. Session 13 — Leadership Architecture Onboarding

Session 13 will be a formal architecture-transition and onboarding session.

Its purpose is not primarily to investigate a new Enron evidential question.

Its purpose is to test whether a newly introduced Pilot Leader can be placed into the Dossier Space environment using controlled documentation rather than inherited conversational memory.

The session will establish and validate the new operating structure:

Pilot Leader → Lumo or Mistral

Human Operator → Ken Tombs

Coding & Architecture Adviser → Claude Chat

Execution → Windows PowerShell / Python / Claude Code

Independent Assurance → Leonard / ChatGPT

Session 13 should therefore test the **transferability of pilot leadership itself**.

23. Proposed Session 13 Objectives

Session 13 should determine whether a candidate Pilot Leader can:

1. review the induction material and GitHub repository;
 2. reconstruct the material current state of the pilot;
 3. identify its own role correctly;
 4. recognise that it is **not the coder**;
 5. distinguish Claude Chat from Claude Code;
 6. understand PowerShell, Python and Claude Code as execution routes;
 7. identify when existing capability is sufficient;
 8. identify when a coding requirement must be referred to Claude Chat;
 9. provide coherent commands for a controlled test operation;
 10. interpret the resulting output;
 11. maintain the human-in-the-loop model;
 12. identify governance constraints and uncertainties;
 13. avoid silently redesigning the architecture;
 14. and produce an auditable account of its onboarding.
-

24. Candidate Leader Induction Task

Each candidate AI should independently review the designated GitHub materials and produce an **Induction Understanding Note** containing:

1. its understanding of the purpose of Dossier Space;

2. its understanding of the Pilot Leader role;
3. what the Pilot Leader must not do;
4. the role of the Human Operator;
5. the role of Claude Chat;
6. the role of Claude Code;
7. the role of Windows PowerShell and Python;
8. the role of External Assurance;
9. the current state of the pilot;
10. the principal governance constraints;
11. any apparent conflicts or ambiguities in the repository;
12. any assumptions it would otherwise have needed to make;
13. and its proposed method for directing a simple controlled Dossier Space operation.

The same induction materials and task should be provided independently to Lumo and Mistral.

25. Session 13 Practical Test

After induction, the candidate Leader should be asked to direct a **small, bounded and already understood operation**.

The Leader should:

1. state the evidential or validation objective;
2. select an appropriate existing execution route;
3. provide the Human Operator with the necessary PowerShell, Python or Claude Code instruction;
4. receive the resulting output;
5. interpret the result;
6. identify any limitation;
7. and decide whether the task is complete.

The practical test should preferably use existing validated capability so that the session tests **leadership transfer rather than new software development**.

If the Leader attempts to solve the task by writing new code unnecessarily, this should itself be treated as an architectural observation.

26. Successful Session 13 Criterion

A successful result would demonstrate that a newly introduced AI can enter the Dossier Space Pilot without inherited conversational memory, reconstruct the material project state from controlled documentation, correctly distinguish leadership from coding and execution, and direct a controlled operation using the existing technical environment.

In particular, the Leader should demonstrate that it can:

think about the investigation without becoming the programmer.

It should be capable of providing appropriate PowerShell, Python or Claude Code commands while recognising that substantive code creation belongs to Claude Chat.

Differences between candidate Leaders are acceptable and potentially informative.

The test is not seeking identical reasoning.

It is seeking **consistent grounding in the same architecture, evidence base and governance rules.**

27. Core Rule for the New Leader

If uncertain:

Check the repository before reconstructing the past from memory or inference.

If the record remains unclear:

Expose the uncertainty rather than silently resolving it.

If the required operation already exists:

Direct it through PowerShell, Python or Claude Code.

If new code is required:

Define the requirement and refer it to Claude Chat.

If architecture would change:

Propose, review and approve the change before implementation.

Above all:

The Pilot Leader leads the investigation. It does not cut code.

End of Induction Brief
