

Session 13 agent-operation account

This is an account reconstructed from the agent's tool-operation history, current filesystem metadata and hashes. It is **not Git-verified completeness**: the relevant Dossier Space directory is not inside an accessible Git working tree.

1. Session 13 audit log

Final path:

[session_13_audit_log.txt](E:/AAll XPlain/Dossier Space Pilot/Governance Ledger/session_13_audit_log.txt)

- Agent action: modified
- Agent change: added and correctly positioned KF-S13-09
- Initially created by: user-operated PowerShell, not by the agent
- Current size: 3,909 bytes
- Current SHA-256:
138A32B5C84C7B58346851DD83EEA879899CC6B2A766AA43705FED18EBD1328E
- Created: 2026-08-26 16:18:19.0467177 +02:00
- Last modified: 2026-08-26 16:30:29.2459243 +02:00

The agent first inserted KF-S13-09 at the wrong position, detected that during verification, and moved the same block after KF-S13-08. Both operations affected only this file.

2. Final transportability assessment

Final path:

[DS-20260826-S13-Final-Transportability-Assessment.md](E:/AAll XPlain/Dossier Space Pilot/Session GIT Deliverables/DS-20260826-S13-Final-Transportability-Assessment.md)

- Agent actions: created in workspace, then moved to final location
- Current size: 19,025 bytes
- Current SHA-256:
DCF6C70FBE8D76064107B05270F3D7717C4AD8523B19FE7365E4031D65E2E853
- Created at destination: 2026-08-26 16:40:30.8297243 +02:00
- Current last modification: 2026-08-26 16:50:50.6030243 +02:00

At the time of the agent's move, the file was 18,710 bytes with SHA-256:

39EDB09DC0F92E9AC4D6FD71B2D09E6534E9AA9D649E5130F19502F1AEEA96B4

The later size, timestamp and current hash show that it was subsequently modified after the move. The agent's attempted insertion of the Git-verification limitation failed and made no change; the current metadata is consistent with the limitation later being added outside that failed agent operation.

3. Temporary assessment path

Former path:

C:\Users\ktomb\Documents\Codex\2026-08-26\slack-plugin-slack-openai-curated-remote\work\DS-20260826-S13-Final-Transportability-Assessment.md

- Agent actions: created, then moved
- Current status: does not exist
- Destination: final assessment path above
- SHA-256 immediately before/after the move:
39EDB09DC0F92E9AC4D6FD71B2D09E6534E9AA9D649E5130F19502F1AEEA96B4

The source disappeared as the normal result of the move; it was not independently deleted.

Failed staging path

C:\Users\ktomb\Documents\Codex\2026-08-26\slack-plugin-slack-openai-curated-remote\work\DS-20260826-S13-Final-Transportability-Assessment.edit.md

This path was proposed during a later edit attempt but was never created.

Completeness statement

According to the agent-operation history, the only project files changed by the agent were:

1. Governance Ledger\session_13_audit_log.txt
2. Session GIT Deliverables\DS-20260826-S13-Final-Transportability-Assessment.md

No project file was deleted. The only moved-away path was the temporary workspace copy of the assessment. No corpus file, ADR, architecture record, existing finding or other governance file was changed.

Because Git verification was unavailable, this statement is limited to recorded agent operations corroborated by current filesystem evidence; it is not a repository-wide Git proof.

My assurance verdict is **accept with targeted corrections**. The central conclusion is well supported and suitable for the article. It does not need another substantive reconstruction.

Three points must be corrected before closure:

1. **Cold-test qualification**

The assessment says reconstruction occurred “without a new induction.” That is too absolute because Codex encountered the newly created, auto-loaded `AGENTS.md`.

The accurate finding is:

No formal human-supplied induction was provided during the cold phase. However, the environment contained a newly created Codex-oriented `AGENTS.md`, making the cold context potentially contaminated. Codex subsequently detected and rejected its unsupported authority.

Thus we demonstrated reconstruction **despite misleading context**, not a perfectly clean absence of onboarding.

2. **Git scope must be reconciled**

The report says no accessible `.git` repository existed, but also describes `AGENTS.md` as absent from a Git index, untracked and not ignored. Those claims may relate to different directories, but this is not explained.

DL must identify:

- Where the Git index used to assess `AGENTS.md` was located.
- Which directory produced `fatal: not a git repository`.
- Whether Git verification applied only to `AGENTS.md`, or to the Session 13 deliverables as well.

3. **Operational interventions are missing**

The final report should record:

- The stalled context-picker setup.
- Windows directory-write restrictions.
- The failed file patch/write attempt.
- Ken’s manual addition to the audit log.
- Creation of the final assessment through a separately approved, bounded file move.
- The inability to produce a repository-wide Git diff.

These do not undermine the result; they demonstrate that transportability includes permissions, interfaces and custody of outputs—not just intellectual reconstruction
